Ekspresja receptora CD23⁺ na limfocytach B w tkance przerosłych migdałków gardłowych u dzieci chorych na wysiękowe zapalenie ucha

Expression of receptor CD23⁺ on limphocytes B in hypertrophy adenoids in children with otitis media with effusion

Karol Ratomski, Jolanta Wysocka, Elżbieta Hassmann-Poznańska, Edwina Kasprzycka

Summary

Tonsil pharyngeal is stimulated chronic by pathogens can be cause hypertrofied; whose often is companions to otitis media with effusion. Subpopulation dominates in tonsil pharyngeal are lymphocytes B, and their markers activation are expression of antigen CD23⁺. The aim of this study was finding dependence between otitis media with effusion and coexistent hypertrophy adenoids, and percentage of lymphocytes CD19⁺ with expression of antigen CD23⁺ in hypertrophy adenoids. In the study showed higher significant percentage of lymphocytes CD19⁺/CD23⁺ at children in otitis media with effusion (20.08±2.93) with reference to comparative group, which was only hypertrophy adenoid (18.16±2.25). Percentage lymphocytes B (CD23⁺) were the highest (20.01±5.81) in children subgroup above 5 years old with otitis media with effusion, and lowest (17.36±2.78) in children comparative subgroup above 5 years old. As regards on different functions of antigen CD23⁺ the assessment of percentage lymphocytes B with expression of CD23⁺ can be additional marker in course immunological and inflammatory processes to occur in hypertrophy adenoids at children are sick otitis media with effusion.
