**ABSTRACT**

Primary intra osseous mucoepidermoid carcinoma arising from jaw is an extremely rare condition accounting less than 2% of all mucoepidermoid carciomas. In the jaw, it occurs more commonly in mandible than maxilla. They are low grade cancers and affect jaw as uni- or multi locular radiographic lesions. Here we discuss a rare case of giant cystic primary intra cystic mucoepidermoid carcinoma of the mandible which was excised in toto. Here we discuss the clinical features, radiological and histological characteristics of this rare lesion and review the literature.
